## ABSTRACT

The hidden Markov model consists of a pair of an unobserved Markov chain $\left\{\mathrm{X}_{\mathrm{k}}\right\}$ and an observation process $\left\{\mathrm{Y}_{\mathrm{k}}\right\}$. In this research, the crosses of diploid plant apply the model. The Markov chain $\left\{\mathrm{X}_{\mathrm{k}}\right\}$ represents genetic structure, which is genotype of the $\mathrm{k}^{\text {th }}$ generation of an organism. The observation process $\left\{\mathrm{Y}_{\mathrm{k}}\right\}$ represents the appearance or the observed trait, which is the phenotype of the $\mathrm{k}^{\text {th }}$ generation of an organism. Since it is unlikely to observe the genetic structure directly, the Hidden Markov model can be used to model pairs of events and unobservable their causes. Forming the model requires the use of the theory of heredity from Mendel. This model can be used to explain the characteristic of true breeding on crosses of diploid plants. The more traits crossed, the smaller probability of plants having a dominant phenotype in that period. Monohybrid, dihybrid, and trihybrid crosses have a dominant phenotype probability of $99 \%$ in the seventh, eighth, and ninth generations, with the condition of previous generations having a dominant phenotype. But in seventh generation, monohybrid crosses only have the probability of an optimal genotype of 50\%, dihybrid crosses have a probability of an optimal genotype of $25 \%$ in the eighth generation, and trihybrid crosses have a probability of an optimal genotype of $12.5 \%$ in the ninth generation.

## 1. INTRODUCTION

Heredity is a trait inheritance or forwarding from one generation to the next. For thousand of years, the principles of heredity and variation have been exploited by farmers so they can produce plants and animals with desired traits. Gregor Mendel, who found the first acceptable theory of the trait inheritance system, proposed several hypotheses about the inheritance of genetic material from the parent to the offspring. According to Mendel, for each character, the organism inherits two alleles, one from each parent. He makes this deduction without knowing about the roles or even the existence of chromosomes. Any cell with two chromosome sets is called a diploid cell, where one set is inherited from each parent [1].

Although this law of Mendel's can provide hypotheses about the inheritance of genetic material from the parent to the offspring, searching for the trait is only done based on the observed appearance in the organism. The characteristics of an organism do not always reveal its genetic composition. Therefore, the appearance of the observed trait in the organism, namely phenotype, can be distinguished from its genetic structure, namely genotype. This genetic structure is unlikely to be observed. The hidden Markov model can help model pairs of events and their causes that cannot be observed directly [2]. This models have also been used in bioinformatics and biochemistry, some of them are [3], [4], [5], [6], [7], [8], [9], [10], [11], [12], [13].

In the state space of the finite observation process and the time index is countable, the model is known as the discrete version of the hidden Markov model [2]. Thorvaldsen [14] in his research, revealed interesting ideas about the role of hidden Markov models in bioinformatics. In his research, he found that the hidden Markov model can be applied to Mendel's experiments. In this research the model is applied to crosses of diploid plant and used to explain the characteristic of true-breeding in diploid plant crosses. The true-breeding generation of a plant can help to find seeds that have both feasible appearances and genetics.

## 2. RESEARCH METHODS

### 2.1 Discrete Hidden Markov Models

The hidden Markov model $(X, Y)$ is a model generated by a Markov chain $X=\left\{X_{k}\right\}_{k \in N}$ that is unobserved and an observation process $Y=\left\{Y_{k}\right\}_{k \in N}$. The observation is influanced by $X_{k}$, while $X_{k}$ is influenced by $X_{k-1}$. This relationship is illustrated in Figure 1.

Figure 1. Hidden Markov Model ( $\boldsymbol{X}, \boldsymbol{Y}$ )
Characteristics of hidden Markov model:

1) The sequence $\left\{X_{k}\right\}_{k \in N}$ forms a Markov chain with finite state space $S_{X}=\{1,2, \cdots, N\}$ and $\boldsymbol{A}=\left(a_{i j}\right)_{N \times N}$ is a matrix of transition probability with

$$
a_{i j}=P\left(X_{k+1}=j \mid X_{k}=i\right)
$$

for $i, j=1,2, \cdots, N ; a_{i j} \geq 0$ and $\sum_{j=1}^{N} a_{i j}=1$. Furthemore, $\pi=\left(\pi_{i}\right)_{N \times 1}$ is a probability matrix of the initial state with

$$
\pi_{i}=P\left(X_{1}=i\right)
$$

for $i=1,2, \cdots, N$ and $\sum_{i=1}^{N} \pi_{i}=1$.
2) The sequence $\left\{Y_{k}\right\}_{k \in N}$ is the observation process with state space $S_{Y}=\{1,2, \cdots, M\}$. The relationship of $\left\{X_{k}, Y_{k}\right\}_{k \in N}$ process is represented by emission probability matrix $\boldsymbol{B}=\left(b_{i}(j)\right)_{N \times M}$ with

$$
b_{i}(j)=P\left(Y_{k}=j \mid X_{k}=i\right)
$$

for $i=1,2, \cdots, N ; j=1,2, \cdots, M ; b_{i}(j) \geq 0$ and $\sum_{j=1}^{M} b_{i}(j)=1$.
3) It is assumed that $\left\{Y_{k} \mid X_{k}\right\}_{k \in N}$ are independent, this means
$P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K} \mid X_{1}=x_{1}, \cdots, X_{K}=x_{K}\right)=\prod_{k=1}^{K} P\left(Y_{k}=y_{k} \mid X_{k}=x_{k}\right)$

Therefore, based on those characteristics, we obtain a set of parameters as the characteristic of the hidden Markov model, namely

$$
\lambda=(\boldsymbol{A}, \boldsymbol{B}, \boldsymbol{\pi}) .
$$

Given observation sequence $y_{1}, y_{2}, \cdots, y_{K} ; y_{k} \in S_{y}$ for $k=1,2, \cdots, K$ and $\lambda=(\boldsymbol{A}, \boldsymbol{B}, \boldsymbol{\pi})$. There are three main problems in the hidden Markov model. The first is calculating the probability of the emergence of an observation sequence $y_{1}, y_{2}, \cdots, y_{K}$ which is solved by forward and backward algorithms. The second problem is determining the sequence of a hidden state $x_{1}, x_{2}, \cdots, x_{K}$ that is optimally solved by the Veterbi algorithm. The third problem is estimating the parameters of the hidden Markov model $\lambda=(\boldsymbol{A}, \boldsymbol{B}, \boldsymbol{\pi})$, so that $P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K} \mid \lambda\right)$ is maximum which is done with the Baum-Welch algorithm [15].

### 2.2 Forward and Backward Algorithms

The probability of the appearance of an observation sequence $y_{1}, y_{2}, \cdots, y_{K}$ given $\lambda=(\boldsymbol{A}, \boldsymbol{B}, \boldsymbol{\pi})$ i.e $P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K} \mid \lambda\right)$ is calculated using forward and backward algorithms. Defined variables

$$
\begin{equation*}
\alpha_{k}(j)=P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}, X_{k}=j \mid \lambda\right), \tag{1}
\end{equation*}
$$

for $k=1,2, \cdots, K$. The forward algorithm consists of three stages:

1) Initialization stage

$$
\begin{aligned}
\alpha_{1}(j) & =P\left(Y_{1}=y_{1}, X_{1}=j \mid \lambda\right) \\
& =P\left(X_{1}=j \mid \lambda\right) P\left(Y_{1}=y_{1} \mid X_{1}=j, \lambda\right) \\
& =\pi_{j} b_{j}\left(y_{1}\right), \text { for } j=1,2, \cdots, N .
\end{aligned}
$$

2) Induction stage

$$
\begin{aligned}
\alpha_{k+1}(j) & =P\left(Y_{1}=y_{1}, \cdots, Y_{k+1}=y_{k+1}, X_{k+1}=j \mid \lambda\right) \\
& =\left(\sum_{i=1}^{N} \alpha_{k}(i) a_{i j}\right) b_{j}\left(y_{k+1}\right), \quad \text { for } j=1,2, \cdots, N \text { and } k=1,2, \cdots, K-1 .
\end{aligned}
$$

3) Termination stage

$$
P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K} \mid \lambda\right)=\sum_{j=1}^{N} \alpha_{K}(j) .
$$

Defined variables

$$
\begin{equation*}
\beta_{k}(j)=P\left(Y_{k+1}=y_{k+1}, \cdots, Y_{K}=y_{K} \mid X_{k}=j, \lambda\right), \tag{2}
\end{equation*}
$$

for $k=1,2, \cdots, K$. The backward algorithm consists of three stages:

1) Initialization stage

$$
\begin{aligned}
\beta_{K}(j) & =P\left(Y_{K+1}=y_{K+1} \mid X_{K}=j, \lambda\right) \\
& =1, \quad \text { for } j=1,2, \cdots, N .
\end{aligned}
$$

2) Induction stage

$$
\begin{aligned}
\beta_{k}(j) & =P\left(Y_{k+1}=y_{k+1}, \cdots, Y_{K}=y_{K} \mid X_{k}=j, \lambda\right) \\
& =\sum_{i=1}^{N} b_{i}\left(y_{k+1}\right) \beta_{k+1}(j) a_{j i}, \quad \text { for } j=1,2, \cdots, N \text { and } k=K-1, K-2, \cdots, 2,1 .
\end{aligned}
$$

3) Termination stage

$$
P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K} \mid \lambda\right)=\sum_{j=1}^{N} \pi_{j} b_{j}\left(y_{1}\right) \beta_{1}(j) .
$$

Forward and backward algorithms produce probability of observation sequence as follows

$$
\begin{align*}
L_{K} & =P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K} \mid \lambda\right) \\
& =\sum_{j=1}^{N} P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}, X_{k}=j \mid \lambda\right) \\
& =\sum_{j=1}^{N} \alpha_{k}(j) \beta_{k}(j), \quad \text { for } k=1,2, \cdots, K . \tag{3}
\end{align*}
$$

### 2.3 Veterbi Algorithm

The selection of hidden state sequence $x_{1}, x_{2}, \cdots, x_{K}$ in order to optimize the probability of hidden state is done by using Veterbi algorithm. Defined variables

$$
\begin{aligned}
\delta_{k}(j) & =\max _{x_{1}, \cdots, x_{k-1}} P\left(Y_{1}=y_{1}, \cdots, Y_{k}=y_{k}, X_{1}=x_{1}, \cdots, X_{k}=j \mid \lambda\right) \\
& =\left(\max _{i=1,2, \cdots, N} \delta_{k-1}(i) a_{i j}\right) b_{j}\left(y_{k}\right), \quad \text { for } k=1,2, \cdots, K
\end{aligned}
$$

The Veterbi algorithm consists of four stages:

1) Initialization stage

$$
\begin{aligned}
\delta_{1}(j) & =P\left(Y_{1}=y_{1}, X_{1}=j\right) \\
& =P\left(Y_{1}=y_{1} \mid X_{1}=j\right) P\left(X_{1}=j\right) \\
& =\pi_{j} b_{j}\left(y_{1}\right), \\
\psi_{1}(j) & =\arg \max _{i=1,2, \cdots, N} \delta_{0}(i) a_{i j} \\
& =\emptyset .
\end{aligned}
$$

2) Recursion stage
$\delta_{k}(j)=b_{j}\left(y_{k}\right) \max _{1 \leq i \leq N}\left\{a_{i j} \delta_{k-1}(i)\right\}$,
$\psi_{k}(j)=\arg \max _{1 \leq i \leq N}\left\{a_{i j} \delta_{k-1}(i)\right\}$, for $k=2,3, \cdots, K-1$.
3) Termination stage

$$
\begin{aligned}
P^{*} & =\max _{1 \leq i \leq N}\left\{\delta_{K}(i)\right\} \\
x_{K}^{*} & =\arg \max _{1 \leq i \leq N}\left\{\delta_{K}(i)\right\}
\end{aligned}
$$

4) Backtracking stage

$$
x_{k}{ }^{*}=\psi_{k+1}\left(x_{k+1}{ }^{*}\right), \text { for } k=K-1, K-2, \cdots 2,1
$$

The backtracking stage allows the optimal hidden state sequence to be found from the last point that is stored at the recursion stage.

### 2.4 Baum-Welch Algorithm

The problem that must be solved on the third problem is to obtain the best model that can explain an observation sequence $y_{1}, y_{2}, \cdots, y_{K}$. To solve this last problem, the Baum-Welch algorithm is used. Estimation problems are solved by the Maximum Likelihood (ML) method.

Defined likelihood function

$$
\mathcal{L}\left(\lambda \mid Y_{1}=y_{1}, Y_{2}=y_{2}, \cdots, Y_{K}=y_{K}\right)=P\left(Y_{1}=y_{1}, Y_{2}=y_{2}, \cdots, Y_{K}=y_{K} \mid \lambda\right)
$$

and

$$
\hat{\lambda}_{M L}=\arg \max _{\lambda} P\left(Y_{1}=y_{1}, Y_{2}=y_{2}, \cdots, Y_{K}=y_{K} \mid \lambda\right)
$$

Finding $\hat{\lambda}_{M L}$ cannot be done analytically. Hence, the numerical recursive method of Expectation Maximization (EM) is used. An initial value

$$
\lambda=(\boldsymbol{A}, \boldsymbol{B}, \boldsymbol{\pi})
$$

is given as the characteristic of the hidden Markov model by using Mendel's law. Then, we find the new estimation model parameter namely $\hat{\lambda}$. Furthermore, the $\hat{\lambda}$ model can be said to be a better model then the $\lambda$ model if it fulfills

$$
P\left(Y_{1}=y_{1}, Y_{2}=y_{2}, \cdots, Y_{K}=y_{K} \mid \hat{\lambda}\right) \geq P\left(Y_{1}=y_{1}, Y_{2}=y_{2}, \cdots, Y_{K}=y_{K} \mid \lambda\right)
$$

If this process is done repeatedly using $\hat{\lambda}$ as $\lambda$ for the new process, then the better probability value $Y_{1}=$ $y_{1}, Y_{2}=y_{2}, \cdots, Y_{K}=y_{K}$ can be determined. The process is carried out until $\hat{\lambda}$, which maximizes probabilities
$Y_{1}=y_{1}, Y_{2}=y_{2}, \cdots, Y_{K}=y_{K}$, is obtained. The final result of re-estimating the parameters of the hidden Markov model is called the ML estimator.

The formula to re-estimate the parameters of the model is obtained by maximizing Baum-Welch's function

$$
\begin{aligned}
\mathcal{Q}(\lambda, \hat{\lambda})= & \sum_{x} P\left(X_{1}=x_{1}, \cdots, X_{K}=x_{K} \mid Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}, \lambda\right) \\
& \log \left[P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}, X_{1}=x_{1}, \cdots, X_{K}=x_{K} \mid \hat{\lambda}\right)\right]
\end{aligned}
$$

Maximizing Baum-Welch's function can cause an increase in the likelihood function, namely

$$
\max _{\lambda}[Q(\lambda, \hat{\lambda})] \rightarrow P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K} \mid \hat{\lambda}\right) \geq P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K} \mid \lambda\right)
$$

The sequence $\left\{P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K} \mid \hat{\lambda}\right)\right\}$ is obtained so that it converges to a local maximum point. The formula to re-estimate the next parameters model can be expressed as an implementation of the EM algorithm.
Start : given an estimator $\lambda=(\boldsymbol{A}, \boldsymbol{B}, \boldsymbol{\pi})$,
Step E : calculate the value

$$
\begin{aligned}
\mathcal{Q}(\lambda, \hat{\lambda})= & \sum_{x} P\left(X_{1}=x_{1}, \cdots, X_{K}=x_{K} \mid Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}, \lambda\right) \\
& \log \left[P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}, X_{1}=x_{1}, \cdots, X_{K}=x_{K} \mid \hat{\lambda}\right)\right]
\end{aligned}
$$

Step M : determine

$$
\hat{\lambda}_{M L}=\arg \max _{\lambda}[Q(\lambda, \hat{\lambda})] \rightarrow P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K} \mid \hat{\lambda}\right) \geq P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K} \mid \lambda\right)
$$

If the sequence $\left\{P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K} \mid \hat{\lambda}\right)\right\}$ converges to a local maximum point, then it is done. Otherwise, $\hat{\lambda}$ is replaced with $\lambda$, then step $E$ is repeated, and so on. Beside that, it is worth to note that in each iteration, there are conditions that must be fulfilled by the parameters of the new hidden Markov model, namely

$$
\begin{equation*}
\sum_{j=1}^{N} \hat{a}_{i j}=1, \sum_{i=1}^{N} \hat{\pi}_{i}=1, \text { and } \sum_{j=1}^{N} \hat{b}_{i}(j)=1 \text { for } i=1,2, \cdots, N \tag{4}
\end{equation*}
$$

Looking at the estimation problem as an optimization constraint function of $P\left(Y_{1}=y_{1}, \cdots, Y_{K}=\right.$ $\left.y_{K} \mid \lambda\right)$, the Lagrange multiplication technique can be a solution to find the value of $\lambda=(\boldsymbol{A}, \boldsymbol{B}, \boldsymbol{\pi})$ that maximizes $P\left(Y_{1}=y_{1}, \cdots, Y_{K}=y_{K} \mid \lambda\right)$. Based on the standard form of Lagrange optimization, Equation (4) is a constraint function and Equation $\mathcal{Q}(\lambda, \hat{\lambda})$ is a maximized objective function. Defined variables

$$
\begin{equation*}
\xi_{k}(i, j)=P\left(X_{k}=i, X_{k+1}=j \mid Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}, \lambda\right) \tag{5}
\end{equation*}
$$

for $i, j=1,2, \cdots, N$ and $k=1,2, \cdots, K$, is probability of $i$ state at $k$ time and $j$ state at $k+1$ time. If the $\lambda$ model and observation sequence is given, by using Equation (1), Equation (2), Equation (3), and Equation (5), can be obtained

$$
\xi_{k}(i, j)=\frac{\alpha_{k}(i) a_{i j} b_{j}\left(y_{k+1}\right) \beta_{k+1}(j)}{\sum_{j=1}^{N} \alpha_{k}(j) \beta_{k}(j)}
$$

Defined variables

$$
\gamma_{k}(i)=P\left(X_{k}=i \mid Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}, \lambda\right)
$$

for $k=1,2, \cdots, K$, is probability of $i$ state at $k$ time if given an observation sequence $Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}$ and $\lambda$ model, so can be obtained

$$
\begin{aligned}
\gamma_{k}(i) & =P\left(X_{k}=i \mid Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}, \lambda\right) \\
& =\frac{\alpha_{k}(i) \beta_{k}(i)}{\sum_{i=1}^{N} \alpha_{k}(i) \beta_{k}(i)}
\end{aligned}
$$

Then, the relationship between $\xi_{k}(i, j)$ and $\gamma_{k}(i)$ is obtained by summing up $\xi_{k}(i, j)$ for each $j$ as follows:

$$
\begin{aligned}
\gamma_{k}(i) & =P\left(X_{k}=i \mid Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}, \lambda\right) \\
& =\sum_{j=1}^{N} \xi_{k}(i, j)
\end{aligned}
$$

for $i=1,2, \cdots, N$ and $k=1,2, \cdots, K$. Summing up $\xi_{k}(i, j)$ on $1 \leq k \leq K-1$ produces the probability value of moving $i$ state to $j$ state until $K-1$ time, as follows:

$$
\sum_{k=1}^{K-1} \xi_{k}(i, j)=\sum_{k=1}^{K-1} P\left(X_{k}=i, X_{k+1}=j \mid Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}, \lambda\right)
$$

Summing up $\gamma_{k}(i)$ on $1 \leq k \leq K-1$ produces the probability value at $i$ state until $K-1$ time, as follows:

$$
\sum_{k=1}^{K-1} \gamma_{k}(i)=\sum_{k=1}^{K-1} P\left(X_{k}=i \mid Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}, \lambda\right)
$$

The formula to re-estimate the parameters of the hidden Markov model is as follows:
$\hat{\pi}_{i}=$ the probability value in $i$ state at $k=1$ time

$$
\begin{aligned}
& =P\left(X_{1}=i \mid Y_{1}=y_{1}, \cdots, Y_{K}=y_{K}, \lambda\right) \\
& =\gamma_{1}(i), \text { for } i=1,2, \cdots, N . \\
\hat{a}_{i j} & =\frac{\text { the transition probability of } i \text { state to } j \text { state until } K-1 \text { time }}{\text { the probability value in } i \text { state until } K-1 \text { time }} \\
& =\frac{\sum_{k=1}^{K-1} \xi_{k}(i, j)}{\sum_{k=1}^{K-1} \gamma_{k}(i)}, \text { for } i=1,2, \cdots, N \text { and } j=1,2, \cdots, K . \\
\hat{b}_{i}(j) & =\frac{\text { the probability of appearance } X_{k}=i \text { and } Y_{k}=j \text { until } K \text { time }}{\text { the probability value in } i \text { state until } K \text { time }} \\
& =\frac{\sum_{k=1, s . t y_{k}=j}^{K} \gamma_{k}(i)}{\sum_{k=1}^{K} \gamma_{k}(i)} .
\end{aligned}
$$

## 3. RESULTS AND DISCUSSION

### 3.1 Mendel's Law

Gregor Mendel developed the theory of inheritance by experimenting with various varieties, which for several generations carried out self-fertilization and only produced the same variety as its parent plant. Plants that have these properties are called true breeding. In his experiments, Mendel crossed two contradicting variations of true breeding in peas. The crossing of two true-breeding varieties is called hybridization. The true-breeding parent is called a parental generation ( $P$ generation), hybrid offspring is called the first filial generation ( $F_{1}$ generation), and the offspring produced from self-fertilization $F_{1}$ hybrids are called the second filial generation ( $F_{2}$ generation). Mendel concluded the result of quantitative analysis of $F_{2}$, which has become the fundamental principle of heredity known as segregation law and free sorting law.

He describes four concepts used to develop a model that explains the pattern of trait inheritance. First, alternative versions of genes (alleles) cause variations in inherited characters. For example, at the color locus of the peas flower, there are alleles of purple flowers and alleles of white flowers. Second, for each character, the organism inherits two alleles, one from each parent. Every somatic cell in a diploid organism has two set of chromosomes, one set inherited from each parent. Third, if the two alleles at a locus are different, then one of them is the dominant allele that determines the organism's appearance, and the other is the recessive allele that has no visible effect on the appearance of the organism. Fourth, at the same time, the law of segregation from Mendel state that two alleles for an inherited character segregate during gametes formation, and eventually, it is at the different gametes.

Organisms that have a pair of identical alleles for a character are called homozygotes. Meanwhile, organisms with two different alleles for a character are called heterozygotes. The characteristics of an organism do not always reveal its genetic composition. Therefore, the appearance of the observed trait in the organism, namely the phenotype, can be distinguished from its genetic structure, namely the genotype. Individuals that are heterozygotes only for one character are called monohybrids, and crosses between heterozygotes are called monohybrid crosses. Likewise, individuals that heterozygotes for two characters are dihybrids, while three characters are called trihybrids. The results of Mendel's dihybrid experiments are the basis of the free sorting law which states that each pair of alleles segregates freely against other alleles during gamete formation [1].

### 3.1.1 Monohybrid Crosses

$P_{1} \quad: A A \times a a$
$F_{1} \quad: \quad A a$
$P_{2}: A a \times A a$
Gamete: $(A, a) \quad(A, a)$
Table 1. The Second Filial Generation of Monohybrid Crosses

|  | $\boldsymbol{A}$ | $\boldsymbol{a}$ |
| :---: | :---: | :---: |
| $\boldsymbol{A}$ | $A A$ | $A a$ |
| $\boldsymbol{a}$ | $A a$ | $a a$ |

The random variable $X_{k}$ is the $k^{t h}$ progenic genotype and $\left\{X_{k}\right\}$ is a Markov chain with state space $S_{X}=\{A A, A a, a a\}$.

The random variable $Y_{k}$ is the $k^{t h}$ progenic phenotype and $\left\{Y_{k}\right\}$ is an observation process with state space $S_{Y}=\{A, a\}$.

The observation $Y_{k}$ is influenced by $X_{k}$, while $X_{k}$ is influenced by $X_{k-1}$. Figure 2 shows this relationship for a case when the observation (phenotype) sequence is $A, A, \cdots, A$.

Figure 2. Hidden Markov Model of Monohybrid Crosses
Based on Figure 2 it is known that in the first generation, there is dominant phenotype $A$ and heterozygote genotype $A a$. The second generation has dominant phenotype $A$, but its genotype is unknown whether it is heterozygote $A a$ or homozygote $A A$. This happens until $k^{t h}$ generation.

The characteristic of hidden Markov model for monohybrid crosses are as follows:

1) The determination of matrix $\boldsymbol{A}$

The first is determining matrix $\boldsymbol{A}=\left(a_{i j}\right)_{N \times N}$. The dimensions of matrix $\boldsymbol{A}$ is determined by the number of state space $S_{X}$, that is $N=3$. Then, $a_{i j}$ represents a conditional probability of genotype $j$ with genotype $i$ given. Index $i$ represents a genotype of an organism at $k+1$ time, while index $j$ represents genotype of an organism at $k$ time. Matrix $\boldsymbol{A}$ is obtained by using Mendel's law (Table 2).

Table 2. The Mendel's Law of Monohybrid Crosses

| $\begin{aligned} & \hline \boldsymbol{A} \boldsymbol{A} \\ & (A) \\ & \hline \end{aligned}$ | $\times$ | $\begin{aligned} & \hline \boldsymbol{A} \boldsymbol{A} \\ & (A) \\ & \hline \end{aligned}$ | $\begin{gathered} \boldsymbol{A a} \\ (A, a) \end{gathered}$ | $\times$ | $\begin{gathered} \boldsymbol{A} \boldsymbol{a} \\ (A, a) \end{gathered}$ | $\begin{aligned} & \hline \boldsymbol{a a} \\ & (a) \end{aligned}$ | $\times$ | $\begin{aligned} & \boldsymbol{a a} \\ & (a) \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| AA 100\% |  |  | $A A\left(\frac{1}{4}\right), A a\left(\frac{1}{2}\right), a a\left(\frac{1}{4}\right)$ |  |  | aa 100\% |  |  |
| $a_{A A, j}=\left[\begin{array}{lll}1 & 0 & 0\end{array}\right]$ |  |  | $a_{A a, j}=\left[\begin{array}{lll}\frac{1}{4} & \frac{1}{2} & \frac{1}{4}\end{array}\right]$ |  |  | $a_{a a, j}=\left[\begin{array}{lll}0 & 0 & 1\end{array}\right]$ |  |  |

So, we have the transition probability matrix as follows:

$$
\boldsymbol{A}=\left[\begin{array}{lll}
a_{A A, A A} & a_{A A, A a} & a_{A A, a a} \\
a_{A a, A A} & a_{A a, A a} & a_{A a, a a} \\
a_{a a, A A} & a_{a a, A a} & a_{a a, a a}
\end{array}\right]=\left[\begin{array}{ccc}
1 & 0 & 0 \\
\frac{1}{4} & \frac{1}{2} & \frac{1}{4} \\
0 & 0 & 1
\end{array}\right] .
$$

2) The determination of matrix $\boldsymbol{B}$

The second characteristic is determining matrix $\boldsymbol{B}=\left(b_{i}(j)\right)_{N \times M}$. The dimensions of matrix $\boldsymbol{B}$ is determined by the number of state space $S_{X}$ and $S_{Y}$, that is $N=3$ and $M=2$. Then, $b_{i}(j)$ represents a conditional probability of phenotype $j$ with genotype $i$ given. Index $i$ represents a genotype of an organism at $k$ time while index $j$ represents phenotype of an organism at the same time. The first column in matrix $\boldsymbol{B}$ tells that type $A A$ and $A a$ of genotype will be observed as phenotype type $A$, whereas the second column
tells that type $a a$ of genotype will be observed as phenotype type $a$. Thus, we have obtained the emission probability matrix as follows:

$$
\boldsymbol{B}=\left[\begin{array}{ll}
b_{A A}(A) & b_{A A}(a) \\
b_{A a}(A) & b_{A a}(a) \\
b_{a a}(A) & b_{a a}(a)
\end{array}\right]=\left[\begin{array}{ll}
1 & 0 \\
1 & 0 \\
0 & 1
\end{array}\right] .
$$

3) The determination of matrix $\boldsymbol{\pi}$

The third is determining matrix $\pi=\left(\pi_{i}\right)_{N \times 1}$. The dimensions of matrix $\pi$ is determined by the number of state space $S_{X}$, that is $N=3$. Then, $\pi_{i}$ represents an initial probability of genotype $i$. Index $i$ represents a genotype of an organism at an initial time. Since Mendel started with a founder population of heterozygote plants, the initial value of $\pi_{i}$ is zero to homozygote plants and one to heterozygote plants. Hence, we have obtained the initializing parameter of matrix $\boldsymbol{\pi}$ for monohybrid crosses, which is as follows:

$$
\pi=\left[\begin{array}{c}
\pi_{A A} \\
\pi_{A a} \\
\pi_{a a}
\end{array}\right]=\left[\begin{array}{l}
0 \\
1 \\
0
\end{array}\right] .
$$

### 3.1.2 Dihybrid Crosses

| $P_{1}$ | $:$ | $A A B B$ | $\times$ | $a a b b$ |
| :--- | :--- | :--- | :---: | :--- |
| $F_{1}$ | $\vdots$ |  | $A a B b$ |  |
| $P_{2}$ | $\vdots$ | $A a B b$ | $\times$ | $A a B b$ |
| Gamete | $(A B, A b, a B, a b)$ | $(A B, A b, a B, a b)$ |  |  |

Table 3. The Second Filial Generation of Dihybrid Crosses

|  | $\boldsymbol{A B}$ | $\boldsymbol{A} \boldsymbol{b}$ | $\boldsymbol{a B}$ | $\boldsymbol{a b}$ |
| :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{A B}$ | $A A B B$ | $A A B b$ | $A a B B$ | $A a B b$ |
| $\boldsymbol{A} \boldsymbol{b}$ | $A A B b$ | $A A b b$ | $A a B b$ | $A a b b$ |
| $\boldsymbol{a} \boldsymbol{B}$ | $A a B B$ | $A a B b$ | $a a B B$ | $a a B b$ |
| $\boldsymbol{a b}$ | $A a B b$ | $A a b b$ | $a a B b$ | $a a b b$ |

The random variable $X_{k}$ is the $k^{\text {th }}$ progenic genotype and $\left\{X_{k}\right\}$ is a Markov chain with state space

$$
S_{X}=\{A A B B, A a B B, a a B B, A A B b, A a B b, a a B b, A A b b, A a b b, a a b b\} .
$$

The random variable $Y_{k}$ is the $k^{t h}$ progenic phenotype and $\left\{Y_{k}\right\}$ is an observation process with state space

$$
S_{Y}=\{A B, A b, a B, a b\} .
$$

The observation $Y_{k}$ is influenced by $X_{k}$, while $X_{k}$ is influenced by $X_{k-1}$. Figure 3 shows this relationship for a case when the observation (phenotype) sequence is $A B, A B, \cdots, A B$.

Figure 3. Hidden Markov Model of Dihybrid Crosses
Based on Figure 3 it is known that in the first generation, there is dominant phenotype $A B$ and heterozygote genotype $A a B b$. The second generation has dominant phenotype $A B$, but its genotype is unknown whether it is heterozygote $A a B B, A A B b, A a B b$ or homozygote $A A B B$. This happens until $k^{\text {th }}$ generation. The initializing parameters of the hidden Markov model on dihybrid crosses can be obtained in the same way with monohybrid crosses. So, we have the initializing parameters as follows:

$$
\boldsymbol{A}=\left[\begin{array}{ccccccccc}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{4} & \frac{1}{2} & \frac{1}{4} & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{4} & 0 & 0 & \frac{1}{2} & 0 & 0 & \frac{1}{4} & 0 & 0 \\
\frac{1}{16} & \frac{1}{8} & \frac{1}{16} & \frac{1}{8} & \frac{1}{4} & \frac{1}{8} & \frac{1}{16} & \frac{1}{8} & \frac{1}{16} \\
0 & 0 & \frac{1}{4} & 0 & 0 & \frac{1}{2} & 0 & 0 & \frac{1}{4} \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{4} & \frac{1}{2} & \frac{1}{4} \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1
\end{array}\right],\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 \\
1 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1
\end{array}\right] \text { and } \boldsymbol{\pi}=\left[\begin{array}{l}
0 \\
0 \\
0 \\
0 \\
1 \\
0 \\
0 \\
0 \\
0
\end{array}\right] .
$$

### 3.1.3 Trihybrid Crosses

| $P_{1}$ | $:$ | $A A B B C C$ | $\times$ | $a a b b c c$ |
| :---: | :---: | :---: | :---: | :---: |
| $F_{1}$ | $\vdots$ |  | $A a B b C c$ |  |
| $P_{2}$ | $\vdots$ | $A B b C c$ | $\times$ | $A a B b C c$ |
| Gamete | $(A B C, A B c, A b C, A b c, a B C, a B c, a b C, a b c)$ |  | $(A B C, A B c, A b C, A b c, a B C, a B c, a b C, a b c)$ |  |

Table 4. The Second Filial Generation of Trihybrid Crosses

| $\boldsymbol{A b C}$ | $A A B b C C$ | $A A B b C c$ | $A A b b C C$ | $A A b b C c$ | $A a B b C C$ | $A a B b C c$ | $A a b b C C$ | $A a b b C c$ |
| $\boldsymbol{A b c}$ | $A A B b C c$ | $A A B b c c$ | $A A b b C c$ | $A A b b c c$ | $A a B b C c$ | $A a B b c c$ | $A a b b C c$ | $A a b b c c$ |
| $\boldsymbol{a B C}$ | $A a B B C C$ | $A a B B C c$ | $A a B b C C$ | $A a B b C c$ | $a a B B C C$ | $a a B B C c$ | $a a B b C C$ | $a a B b C c$ |
| $\boldsymbol{a B c}$ | $A a B B C c$ | $A a B B c c$ | $A a B b C c$ | $A a B b c c$ | $a a B B C c$ | $a a B B c c$ | $a a B b C c$ | $a a B b c c$ |
| $\boldsymbol{a b C}$ | $A a B b C C$ | $A a B b C c$ | $A a b b C C$ | $A a b b C c$ | $a a B b C C$ | $a a B b C c$ | $a a b b C C$ | $a a b b C c$ |
| $\boldsymbol{a b c}$ | $A a B b C c$ | $A a B b c c$ | $A a b b C c$ | $A a b b c c$ | $a a B b C c$ | $a a B b c c$ | $a a b b C c$ | $a a b b c c$ |

The random variable $X_{k}$ is the $k^{t h}$ progenic genotype and $\left\{X_{k}\right\}$ is a Markov chain with state space $S_{X}=\{A A B B C C, A A B B C c, A A B B c c, A A B b C C, A A B b C c, A A B b c c, A A b b C C, A A b b C c, A A b b c c$,

AaBBCC, $A a B B C c, A a B B c c, A a B b C C, A a B b C c, A a B b c c, A a b b C C, A a b b C c, A a b b c c$, $a a B B C C, a a B B C c, a a B B c c, a a B b C C, a a B b C c, a a B b c c, a a b b C C, a a b b C c, a a b b c c\}$.
The random variable $Y_{k}$ is the $k^{t h}$ progenic phenotype and $\left\{Y_{k}\right\}$ is an observation process with state space

$$
S_{Y}=\{A B C, A B c, A b C, A b c, a B C, a B c, a b C, a b c\} .
$$

The observation $Y_{k}$ is influenced by $X_{k}$, while $X_{k}$ is influenced by $X_{k-1}$. Figure 4 shows this relationship for a case when the observation (phenotype) sequence is $A B C, A B C, \cdots, A B C$.

Figure 4. Hidden Markov Model of Trihybrid Crosses
Based on Figure 4 it is known that in the first generation, there is dominant phenotype $A B C$ and heterozygote genotype $A a B b C c$. The second generation has dominant phenotype $A B C$, but its genotype is unknown whether it is heterozygote $A A B B C c, A A B b C C, A A B b C c, A a B B C C, A a B B C c, A a B b C C, A a B b C c$ or homozygote $A A B B C C$. This happens until $k^{t h}$ generation. The initializing parameters of the hidden Markov model on trihybrid crosses can be obtained in the same way with monohybrid crosses. So, we have the initializing parameters as follows:

$$
\begin{gathered}
\boldsymbol{A}_{1}=\left[\begin{array}{cccccc}
\boldsymbol{A}_{\mathbf{1}} & \mathbf{0} & \mathbf{0} \\
\boldsymbol{A}_{\mathbf{2}} & \boldsymbol{A}_{\mathbf{3}} & \boldsymbol{A}_{\mathbf{2}} \\
\mathbf{0} & \mathbf{0} & \boldsymbol{A}_{\mathbf{1}}
\end{array}\right], \boldsymbol{B}=\left[\begin{array}{c}
\boldsymbol{B}_{\mathbf{1}} \\
\boldsymbol{B}_{\mathbf{1}} \\
\boldsymbol{B}_{\mathbf{2}}
\end{array}\right] \text { and } \boldsymbol{\pi}=\left[\begin{array}{c}
\mathbf{0} \\
\boldsymbol{\pi} \boldsymbol{\boldsymbol { I } _ { \mathbf { 1 } }} \\
\mathbf{0}
\end{array}\right] \text { with } \\
\boldsymbol{A}_{\mathbf{1}}=\left[\begin{array}{ccccccccc}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{4} & \frac{1}{2} & \frac{1}{4} & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{4} & 0 & 0 & \frac{1}{2} & 0 & 0 & \frac{1}{4} & 0 & 0 \\
\frac{1}{16} & \frac{1}{8} & \frac{1}{16} & \frac{1}{8} & \frac{1}{4} & \frac{1}{8} & \frac{1}{16} & \frac{1}{8} & \frac{1}{16} \\
0 & 0 & \frac{1}{4} & 0 & 0 & \frac{1}{2} & 0 & 0 & \frac{1}{4} \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{4} & \frac{1}{2} & \frac{1}{4} \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1
\end{array}\right],\left[\begin{array}{cccccccccc}
\frac{1}{4} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{16} & \frac{1}{8} & \frac{1}{16} & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & \frac{1}{4} & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{16} & 0 & 0 & \frac{1}{8} & 0 & 0 & \frac{1}{16} & 0 & 0 \\
\frac{1}{64} & \frac{1}{32} & \frac{1}{64} & \frac{1}{32} & \frac{1}{16} & \frac{1}{32} & \frac{1}{64} & \frac{1}{32} & \frac{1}{64} \\
0 & 0 & \frac{1}{16} & 0 & 0 & \frac{1}{8} & 0 & 0 & \frac{1}{16} \\
0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{4} & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{16} & \frac{1}{8} & \frac{1}{16} \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{4}
\end{array}\right], \\
\boldsymbol{A}_{\mathbf{3}}=\left[\begin{array}{llllllllllllll}
\frac{1}{2} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{8} & \frac{1}{4} & \frac{1}{8} & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & \frac{1}{2} & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{8} & 0 & 0 & \frac{1}{4} & 0 & 0 & \frac{1}{8} & 0 & 0 \\
\frac{1}{32} & \frac{1}{16} & \frac{1}{32} & \frac{1}{16} & \frac{1}{8} & \frac{1}{16} & \frac{1}{32} & \frac{1}{16} & \frac{1}{32} \\
0 & 0 & \frac{1}{8} & 0 & 0 & \frac{1}{4} & 0 & 0 & \frac{1}{8} \\
0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{2} & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{8} & \frac{1}{4} & \frac{1}{8} \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{2}
\end{array}\right], \boldsymbol{B}_{\mathbf{1}}=\left[\begin{array}{lllllllll}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0
\end{array}\right], \\
0
\end{gathered}
$$

Searching for the genotype, from generation to generation, is done to obtain good quality seeds (dominant homogenous of genotype). Although the phenotype that is planted in $k^{t h}$ generation is dominant, it is uncertain whether it is good quality seeds. The fewer generations that are necessary to be planted to obtain quality seeds, the better.

### 3.2 True Breeding Generation in Diploid Plant Crosses

Suppose the discrete hidden Markov model is applied to monohybrid, dihybrid and trihybrid crosses. With forward, backward, Veterbi and Baum-Welch algorithms, and $\boldsymbol{A}, \boldsymbol{B}$, and $\boldsymbol{\pi}$ in Subsection 2.2, 2.3, and 2.4 in Section 2 as initial values which are obtained by Mendel's law, the conditional probability of $P=$ $\left(Y_{k+1}=y_{k+1} \mid Y_{1}=y_{1}, \cdots, Y_{k}=y_{k}\right)$ and $P=\left(X_{1}=x_{1}, \cdots, X_{k}=x_{k} \mid Y_{1}=y_{1}, \cdots, Y_{k}=y_{k}\right)$ can be calculated as follows:

### 3.2.1 Monohybrid Crosses

We have obtained the optimal value of $\hat{\lambda}=(\widehat{\boldsymbol{A}}, \widehat{\boldsymbol{B}}, \widehat{\boldsymbol{\pi}})$ for monohybrid crosses over 2734 plants during twenty generations by using package Mathematica 11 software, as follows:

$$
\widehat{\boldsymbol{A}}=\left[\begin{array}{ccc}
1 & 0 & 0 \\
0.254892 & 0.49355 & 0.251558 \\
0 & 0 & 1
\end{array}\right], \widehat{\boldsymbol{B}}=\left[\begin{array}{ll}
1 & 0 \\
1 & 0 \\
0 & 1
\end{array}\right], \text { and } \widehat{\boldsymbol{\pi}}=\left[\begin{array}{l}
0 \\
1 \\
0
\end{array}\right] .
$$

Here, we have obtained the conditional probability $P=\left(Y_{k+1}=y_{k+1} \mid Y_{1}=y_{1}, \cdots, Y_{k}=y_{k}\right)$ and $P=$ ( $X_{1}=x_{1}, \cdots, X_{k}=x_{k} \mid Y_{1}=y_{1}, \cdots, Y_{k}=y_{k}$ ) on monohybrid crosses (Table 5). To simplify the notation, it is defined that $Y_{1}{ }^{n}=A$ represents $Y_{1}=A, Y_{2}=A, \cdots, Y_{n}=A$ and $X_{2}{ }^{n}=A A$ represents $X_{2}=A A, X_{3}=$ $A A, \cdots, X_{n}=A A$.

Table 5. The Conditional Probability of Monohybrid Crosses

| Probability | Value | Probability | Value |
| :--- | :--- | :--- | :--- |
| $P\left(Y_{2}=A \mid Y_{1}=A\right)$ | 0.748442 | $P\left(X_{1}=A a, X_{2}=A A \mid Y_{1}{ }^{2}=A\right)$ | 0.340563 |

| $P\left(Y_{16}=A \mid Y_{1}{ }^{15}=A\right)$ | 0.999975 | $P\left(X_{1}=A a, X_{2}{ }^{16}=A A \mid Y_{1}^{16}=A\right)$ | 0.506437 |
| $P\left(Y_{17}=A \mid Y_{1}{ }^{16}=A\right)$ | 0.999987 | $P\left(X_{1}=A a, X_{2}{ }^{17}=A A \mid Y_{1}{ }_{17}=A\right)$ | 0.506444 |
| $P\left(Y_{18}=A \mid Y_{1}{ }^{17}=A\right)$ | 0.999994 | $P\left(X_{1}=A a, X_{2}{ }^{18}=A A \mid Y_{1}{ }^{18}=A\right)$ | 0.506447 |
| $P\left(Y_{19}=A \mid Y_{1}^{18}=A\right)$ | 0.999997 | $P\left(X_{1}=A a, X_{2}{ }^{19}=A A \mid Y_{1}{ }^{19}=A\right)$ | 0.506448 |
| $P\left(Y_{20}=A \mid Y_{1}{ }^{19}=A\right)$ | 0.999998 | $P\left(X_{1}=A a, X_{2}{ }^{20}=A A \mid Y_{1}{ }^{20}=A\right)$ | 0.506449 |

From Table 5, it is known that the seventh generation monohybrid crosses has the probability of a dominant phenotype of $99 \%$ but the probability of an optimal genotype is only $50 \%$. With more generations of plants, the probability of the plants having a dominant phenotype and an optimal genotype is bigger. However, the increase is very slow.

### 3.2.2 Dihybrid Crosses

We have obtained the optimal value of $\hat{\lambda}=(\widehat{\boldsymbol{A}}, \widehat{\boldsymbol{B}}, \widehat{\boldsymbol{\pi}})$ for dihybrid crosses over 2734 plants during twenty generations by using package Mathematica 11 software, as follows:

$$
\begin{gathered}
\widehat{A}=\left[\begin{array}{ccc}
\widehat{\boldsymbol{A}}_{\mathbf{1}} & \mathbf{0} & \mathbf{0} \\
\widehat{\boldsymbol{A}}_{\mathbf{2}} & \widehat{\boldsymbol{A}}_{\mathbf{3}} & \widehat{A}_{\mathbf{4}} \\
\mathbf{0} & \mathbf{0} & \widehat{A}_{\mathbf{5}}
\end{array}\right], \widehat{\boldsymbol{B}}=\left[\begin{array}{l}
\widehat{\boldsymbol{B}}_{\mathbf{1}} \\
\widehat{\boldsymbol{B}}_{\mathbf{1}} \\
\widehat{B}_{\mathbf{2}}
\end{array}\right] \text { and } \widehat{\boldsymbol{\pi}}=\left[\begin{array}{c}
\mathbf{0} \\
\widehat{\boldsymbol{\pi}}_{\mathbf{1}} \\
\mathbf{0}
\end{array}\right] \text { with } \\
\widehat{\boldsymbol{A}}_{\mathbf{1}}=\left[\begin{array}{ccc}
1 & 0 & 0 \\
0.274512 & 0.515042 & 0.210446 \\
0 & 0 & 1
\end{array}\right], \widehat{\boldsymbol{A}}_{\mathbf{2}}=\left[\begin{array}{cc}
0.257295 & 0 \\
0.066717 & 0.117863 \\
0 & 0.065342 \\
0 & 0 \\
0.266882
\end{array}\right], \\
\widehat{\boldsymbol{A}}_{\mathbf{3}}=\left[\begin{array}{ccc}
0.507058 & 0 & 0 \\
0.12782 & 0.241037 & 0.125859 \\
0 & 0 & 0.48594
\end{array}\right], \widehat{A}_{\mathbf{4}}=\left[\begin{array}{ccc}
0.235647 & 0 & 0 \\
0.064249 & 0.132817 & 0.058296 \\
0
\end{array}\right], \\
\widehat{\boldsymbol{A}}_{\mathbf{5}}=\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
0.241372 & 0.501032 & 0.257596 \\
0 & 0 & 1
\end{array}\right], \widehat{\boldsymbol{B}}_{\mathbf{1}}=\left[\begin{array}{llll}
1 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0
\end{array}\right], \widehat{\boldsymbol{B}}_{\mathbf{2}}=\left[\begin{array}{cccc}
0 & 1 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1
\end{array}\right] \text { and } \widehat{\boldsymbol{\pi}}_{\mathbf{1}}=\left[\begin{array}{l}
0 \\
1 \\
0
\end{array}\right] .
\end{gathered}
$$

Here, we have obtained the conditional probability $P=\left(Y_{k+1}=y_{k+1} \mid Y_{1}=y_{1}, \cdots, Y_{k}=y_{k}\right)$ and $P=$ ( $X_{1}=x_{1}, \cdots, X_{k}=x_{k} \mid Y_{1}=y_{1}, \cdots, Y_{k}=y_{k}$ ) on dihybrid crosses (Table 6). To simplify the notation, it is defined that $Y_{1}^{n}=A B$ represents $Y_{1}=A B, Y_{2}=A B, \cdots, Y_{n}=A B$ and $X_{2}{ }^{n}=A A B B$ represents $X_{2}=$ $A A B B, X_{3}=A A B B, \cdots, X_{n}=A A B B$.

Table 6. The Conditional Probability of Dihybrid Crosses

| Probability | Value | Probability | Value |
| :--- | :--- | :--- | :--- |
| $P\left(Y_{2}=A B \mid Y_{1}=A B\right)$ | 0.553437 | $P\left(X_{1}=A a B b, X_{2}=A A B B \mid Y_{1}{ }^{2}=A B\right)$ | 0.120550 |
| $P\left(Y_{3}=A B \mid Y_{1}{ }^{2}=A B\right)$ | 0.706268 | $P\left(X_{1}=A a B b, X_{2}{ }^{3}=A A B B \mid Y_{1}{ }^{3}=A B\right)$ | 0.170686 |

| $P\left(Y_{16}=A B \mid Y_{1}{ }^{15}=A B\right)$ | 0.999936 | $P\left(X_{1}=A a B b, X_{2}{ }^{16}=A A B B \mid Y_{1}{ }^{16}=A B\right)$ | 0.252972 |
| $P\left(Y_{17}=A B \mid Y_{1}{ }^{16}=A B\right)$ | 0.999967 | $P\left(X_{1}=A a B b, X_{2}{ }^{17}=A A B B \mid Y_{1}{ }^{17}=A B\right)$ | 0.252980 |
| $P\left(Y_{18}=A B \mid Y_{1}{ }^{17}=A B\right)$ | 0.999983 | $P\left(X_{1}=A a B b, X_{2}{ }^{18}=A A B B \mid Y_{1}{ }^{18}=A B\right)$ | 0.252984 |
| $P\left(Y_{19}=A B \mid Y_{1}{ }^{18}=A B\right)$ | 0.999992 | $P\left(X_{1}=A a B b, X_{2}{ }^{19}=A A B B \mid Y_{1}{ }^{19}=A B\right)$ | 0.252986 |
| $P\left(Y_{20}=A B \mid Y_{1}{ }^{19}=A B\right)$ | 0.999996 | $P\left(X_{1}=A a B b, X_{2}{ }^{20}=A A B B \mid Y_{1}{ }^{20}=A B\right)$ | 0.252987 |

From Table 6, it is known that the eighth generation dihybrid crosses has the probability of a dominant phenotype of $99 \%$ but the probability of an optimal genotype is only $25 \%$. With more generations of plants, the probability of the plants having a dominant phenotype and an optimal genotype is rising. However, the growth is slow-moving.

### 3.2.3 Trihybrid Crosses

We have obtained the optimal value of $\hat{\lambda}=(\widehat{\boldsymbol{A}}, \widehat{\boldsymbol{B}}, \widehat{\boldsymbol{\pi}})$ for trihybrid crosses over 2734 plants during twenty generations by using package Mathematica 11 software, as follows:

$$
\begin{aligned}
& \widehat{A}=\left[\begin{array}{ccc}
\widehat{A}_{1} & 0 & 0 \\
\widehat{A}_{2} & \widehat{A}_{3} & \widehat{A}_{4} \\
0 & 0 & \widehat{A}_{5}
\end{array}\right], \widehat{B}=\left[\begin{array}{c}
\widehat{B}_{1} \\
\widehat{B}_{1} \\
\widehat{B}_{2}
\end{array}\right] \text { and } \widehat{\pi}=\left[\begin{array}{c}
0 \\

From Table 7, it is known that the ninth generation trihybrid crosses has the probability of a dominant phenotype of $99 \%$ but the probability of an optimal genotype is only $12.5 \%$. With more generations of plants, the probability of the plants having a dominant phenotype and an optimal genotype is increasing. However, the rise is significantly slow.

The more traits that are crossed, the smaller probability of plants having a dominant phenotype in that period. Therefore, although the probability of diploid plants to obtain dominant phenotype reaches $99 \%$ on a generation, the probability of having an optimal genotype for those plants on that generation is tiny.

## 4. CONCLUSIONS

The discrete hidden Markov model can be applied to diploid plant crosses and can be used to explain the characteristic of true breeding. Initializing the parameters to estimate genotype from diploid plants with
the dominant phenotype produces the same genotype for monohybrid, dihybrid, and trihybrid crosses that are heterozygous in the first generation and homozygous dominant in the next generation. The more traits crossed, the smaller probability of plants having a dominant phenotype in that period. Monohybrid, dihybrid, and trihybrid crosses have a dominant phenotype probability of $99 \%$ in the seventh, eighth, and ninth generations, with the condition of previous generations having a dominant phenotype. But in seventh generation, monohybrid crosses only have the probability of an optimal genotype of $50 \%$, dihybrid crosses have a probability of an optimal genotype of $25 \%$ in the eighth generation, and trihybrid crosses have a probability of an optimal genotype of $12.5 \%$ in the ninth generation. Although the probability for diploid plants has obtained a dominant phenotype by $99 \%$ on a generation, the probability of plants having an optimal genotype on that generation is tiny.
